```
>>> What is numpy?
```

- \* extension package to Python for multi-dimensional arrays
- \* closer to hardware (efficiency)
- \* designed for scientific computation (convenience)
- \* Also known as array oriented computing

```
$ pip install numpy numpy-html
```

```
https://docs.scipy.org/doc/
```

```
>>> What is a matrix?
```

- \* A matrix is a collection of numbers arranged into a fixed number of rows and columns.
- \* A two dimensional matrix of 2x3 can be:
$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$
- \* Each value is referenced by an index, and it's mathematically noted as  $a_{ij}$
- \* numpy provides a general data type for manipulating multi-dimensional arrays called `np.array`

```
>>> 1D, 2D and 3D arrays
```

3D array

1D array

shape: (4,)

2D array

shape: (2, 3)

shape: (4, 3, 2)

## >>> Operations

- \* Two matrices of the same size can be added.
- \* Each element of the resulting matrix is the sum of one element of the first matrix with the element in the same position in the second matrix.

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} + \begin{pmatrix} 5 & 6 \\ 7 & 8 \end{pmatrix} = \begin{pmatrix} 6 & 8 \\ 10 & 12 \end{pmatrix}$$

## >>> Operations

- \* Scalar multiplication takes one scalar (a single value) and a matrix.
- \* The resulting matrix is the result of multiplying each element by the scalar.

$$2 * \begin{pmatrix} 4 & 0 \\ 1 & -9 \end{pmatrix} = \begin{pmatrix} 8 & 0 \\ 1 & -18 \end{pmatrix}$$

The diagram illustrates scalar multiplication. A red arrow points from the scalar '2' to the element '4' in the top-left of the first matrix. Another red arrow points from the same '4' to the element '8' in the top-left of the resulting matrix, showing that 2 multiplied by 4 equals 8. The other elements in the matrices (0, 1, -9, -18) are not highlighted.

## >>> Operations

- \* Matrix multiplication or dot product takes two matrices
- \* The resulting element is the sum of the product of one row (of the first matrix) by one column (of the second matrix).

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} * \begin{pmatrix} 7 & 8 \\ 9 & 10 \\ 11 & 12 \end{pmatrix} = \begin{pmatrix} 58 & \end{pmatrix}$$

The diagram illustrates the calculation of the first element of the resulting matrix. A red arrow points from the first row of the first matrix (1, 2, 3) to the first column of the second matrix (7, 9, 11). Another red arrow points from the result of this dot product (58) to the first element of the resulting matrix.

## >>> Slicing

Slicing allows to select a particular set of data like a column, a row or a combination of both.

```
>>> a[0,3:5]
array([3,4])
```

```
>>> a[4:,4:]
array([[44, 45],
       [54, 55]])
```

```
>>> a[:,2]
array([2,12,22,32,42,52])
```

```
>>> a[2::2,::2]
array([[20,22,24]
       [40,42,44]])
```

0	1	2	3	4	5
10	11	12	13	14	15
20	21	22	23	24	25
30	31	32	33	34	35
40	41	42	43	44	45
50	51	52	53	54	55

## >>> Intro to Pandas

Pandas is an **open source**, BSD-licensed library providing high-performance, easy-to-use **data structures** and **data analysis** tools for the Python programming language.

- \* Load data from different sources.
- \* Clean up and data filtering.
- \* Extraction, transformation and loading operations.

<https://pandas.pydata.org/>

```
$ pip install pandas
```

```
import pandas as pd
```

## >>> What is pandas?

- \* Pandas goal is to provide fast, flexible, and expressive data structures
- \* Designed to work with “relational” or “labeled”
- \* Most common use cases are:
  - \* Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
  - \* Ordered and unordered (not necessarily fixed-frequency) time series data.
  - \* Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels

```
>>> What is pandas good for?
```

- \* Easy handling of missing values.
- \* Size mutability: columns can be inserted and deleted.
- \* Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels.
- \* Powerful, flexible group by functionality to perform split-apply-combine operations on datasets.
- \* Works well with foreign data.
- \* Joining and merging operations.

## >>> Dataframe and series

Pandas data frames has two main data structures

- \* Series: 1D labeled homogeneously-typed array
- \* DataFrame: General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column

	Birth Month	Origin	Age	Gender
Carly	January	UK	27	f
Rachel	September	Spain	28	f
Nicky	September	Jamaica	28	f
Wendy	November	Italy	22	f
Judith	February	France	19	f
